THIS PAPER IS NOT TO BE REMOVED FROM THE EXAMINATION HALL

UNIVERSITY OF LONDON

EC2020 ZA

BSc DEGREES AND GRADUATE DIPLOMAS IN ECONOMICS, MANAGEMENT, FINANCE AND THE SOCIAL SCIENCES, THE DIPLOMA IN ECONOMICS AND SOCIAL SCIENCES AND THE CERTIFICATE IN EDUCATION IN SOCIAL SCIENCES

Elements of Econometrics

Thursday 23 May 2019: 10.00 – 13.00

Time allowed: 3 hours

DO NOT TURN OVER UNTIL TOLD TO BEGIN

Candidates should answer **EIGHT** of the following **TEN** questions: **ALL** of the questions in Section A (8 marks each) and **THREE** questions from Section B (20 marks each). **Candidates are strongly advised to divide their time accordingly.**

Extracts from statistical tables are given after the final question on this paper.

Graph paper is provided at the end of this question paper. If used, it must be detached and fastened securely inside the answer book.

A handheld calculator may be used when answering questions on this paper and it must comply in all respects with the specification given with your Admission Notice. The make and type of machine must be clearly stated on the front cover of the answer book.

If more questions are answered than requested, only the first answers attempted will be counted.

UL19/0091

SECTION A

Answer all questions from this section

1. Consider the following regression model

$$Y_t = \beta_0 + \beta_1 X_t + \beta_2 t + \varepsilon_t, \qquad t = 1, ..., T.$$

Both $\{Y_t\}_{t=1}^T$ and $\{X_t\}_{t=1}^T$ are trend stationary processes. The errors $\{\varepsilon_t\}_{t=1}^T$ are independent random variables with zero mean and constant variance.

(a) **(4 marks)** Discuss the concept "trend stationarity" and contrast it to the concept "difference stationarity". In your answer make sure you also explain what stationarity means.

(b) **(4 marks)** Provide a clear interpretation of the parameter β_1. You are told that you can obtain the estimator for β_1 using "detrended" variables only. Discuss this statement.

2. Consider the following ADL(1,1) model relating the crime rate in a particular province, *crime*$_t$, to the clear-up rate (percentage of crimes resulting in a conviction)

$$\textit{crime}_t = \alpha + \rho \textit{crime}_{t-1} + \delta_1 \textit{clearup}_t + \delta_2 \textit{clearup}_{t-1} + u_t, \text{ with } |\rho| < 1$$

where u_t is white noise, an i.i.d. innovation that is uncorrelated to anything in the past.

(a) **(2 marks)** Briefly indicate whether OLS will provide unbiased and consistent parameter estimators.

(b) **(2 marks)** Derive the long run relationship between *crime* and *clearup*.

(c) **(4 marks)** Rewrite the model above in terms of an error correction model (ECM) and interpret its coefficients.

3. Consider the simple linear regression model

$$Y_i = \beta X_i + u_i, \qquad i = 1, ..., n.$$

We assume that the errors $\{u_i\}_{i=1}^n$ are independent normal random variables with zero mean. The regressor $\{X_i\}_{i=1}^n$ is non-stochastic (fixed under repeated sampling). You suspect that the errors exhibit heteroskedasticity.

(a) **(3 marks)** Explain what we mean by the concept of heteroskedasticity. Enhance your answer with the help of a graphical illustration.

(b) **(5 marks)** Suppose you want to test $H_0 : \beta = 1$ against $H_1 : \beta > 1$. Discuss how you would conduct this test based on the OLS estimator, recognizing the presence of heteroskedasticity. Please provide a detailed answer.

4. Consider the simple linear regression model

$$Y_i = \beta_0 + \beta_1 X_i + u_i, \qquad i = 1, ..., n.$$

We assume that the errors $\{u_i\}_{i=1}^n$ are independent random variables with zero mean. The regressor $\{X_i\}_{i=1}^n$ is non-stochastic (fixed under repeated sampling). Under these conditions, the OLS estimator for β_1, $\hat{\beta}_1$, is unbiased. (You are not asked to derive $\hat{\beta}_1$).

(a) **(2 marks)** Explain the concept of unbiasedness of an estimator.

(b) **(4 marks)** Let us consider two other estimators for the slope β_1 :

$$\hat{\beta}_1^{\circ} = \frac{\sum_{i=1}^n (Z_i - \bar{Z})Y_i}{\sum_{i=1}^n (Z_i - \bar{Z})X_i}; \quad \hat{\beta}_1^{*} = \frac{\sum_{i=1}^n (Z_i - \bar{Z})Y_i}{\sum_{i=1}^n (Z_i - \bar{Z})Z_i}$$

where $Z_i = \sqrt{X_i}$ for all i and $\bar{Z} = \frac{1}{n}\sum_{i=1}^n Z_i$. Please indicate whether $\hat{\beta}_1^{\circ}$ and $\hat{\beta}_1^{*}$ are unbiased estimators for β_1. Clearly show your derivations.

(c) **(2 marks)** Briefly indicate how you would choose between the three estimators, $\hat{\beta}_1$, $\hat{\beta}_1^{\circ}$ and $\hat{\beta}_1^{*}$.

5. Consider the OLS estimator for β in the linear regression model

$$Y_i = \beta X_i + \varepsilon_i, \qquad i = 1, ..., n,$$

where $\{(Y_i, X_i)\}_{i=1}^n$ form an i.i.d. sample from a population and the errors are drawn from an **unknown** distribution with mean zero and variance σ^2. You are told that X_i and ε_i are **uncorrelated** (not necessarily independent therefore!).

(a) **(4 marks)** Discuss the importance of convergence in probability.

(b) **(4 marks)** Discuss the importance of convergence in distribution.

SECTION B

Answer three questions from this section.

6. Let us consider how workplace smoking bans affect the incidence of smoking. Below, we use data on 10,000 US indoor workers from 1991 to 1993 taken from "Do Workplace Smoking Bans Reduce Smoking", by Evans et al. (*American Economic Review*, 1999). Let *smoker* be a dummy variable indicating whether a worker smokes (1=yes, 0=no) and *smkban* a dummy variable indicating whether there is a ban on smoking in the workplace (1=yes, 0=no).

   (a) **(6 marks)** The following OLS regression results were obtained

$$\begin{aligned} \widehat{\textit{smoker}} &= \underset{(0.007)}{0.290} - \underset{(0.009)}{0.078}\textit{smkban} \qquad (6.1) \\ n &= 10000,\ R^2 = 0.0078,\ RSS = 1821.59 \end{aligned}$$

   The standard errors (SEs) are in parentheses. Interpret the parameter estimates of the coefficient on *smkban*. Provide the (approximate) 95% confidence interval for the coefficient on *smkban.* How can we use this confidence interval to test the hypothesis that $\beta_{\textit{smkban}} = 0$?

A further specification was considered that included other characteristics of the worker: the age (in years), gender (male/female), ethnicity (black/hispanic/white), and level of education (E1=highschool dropout, E2=highschool graduate, E3=some college, E4=college graduate, E5 Master degree or above). The following OLS regression results were obtained for this multiple linear regression model

$$\begin{aligned} \widehat{\textit{smoker}} &= \underset{(0.019)}{0.201} - \underset{(0.009)}{0.045}\textit{smkban} - \underset{(.009)}{0.033}\textit{female} - \underset{(.0003)}{0.001}\textit{age} - \underset{(.016)}{0.027}\textit{black} \qquad (6.2) \\ &\quad -\underset{(.014)}{0.104}\textit{hispanic} + \underset{(.019)}{0.310}\textit{E1} + \underset{(.012)}{0.224}\textit{E2} + \underset{(.012)}{0.156}\textit{E3} + \underset{(.012)}{0.042}\textit{E4} \\ n &= 10000,\ R^2 = 0.0526,\ RSS = 1736.81 \end{aligned}$$

The SEs are in parentheses.

   (b) **(3 marks)** Compare the coefficient estimates on *smkban* from the simple and multiple regression model in (6.1) and (6.2) and explain why the estimates differ.

   (c) **(5 marks)** Interpret the estimated parameter on E2 (highschool graduate) in (6.2) and indicate how you can obtain its p-value and what information the p-value provides.

   (d) **(6 marks)** Both the simple and multiple regression model suffer from heteroskedasticity. Explain why. What are the implications of heteroskedasticy for the parameter estimates and the standard errors in (6.1) and (6.2)? What can you do to resolve this problem? Explain your answer.

7. In question 6 we considered the linear regression model to study how workplace smoking bans affect the incidence of smoking. Here we consider the results from applying a probit regression of *smoker* (1=yes, 0=no) on *smkban* (1=yes, 0=no) and the other explanatory variables:

```
. probit smoker smkban female age black hispanic E1 E2 E3 E4

Iteration 0:   log likelihood = -5537.1662
Iteration 1:   log likelihood = -5255.1526
Iteration 2:   log likelihood =  -5252.349
Iteration 3:   log likelihood = -5252.3489

Probit regression                               Number of obs     =     10,000
                                                LR chi2(9)        =     569.63
                                                Prob > chi2       =     0.0000
Log likelihood = -5252.3489                     Pseudo R2         =     0.0514
```

smoker	Coef.	Std. Err.	z	P>|z|	[95% Conf.	Interval]

(a) **(5 marks)** It is argued that using the probit regression model is better than using the linear probability model when explaining the binary variable *smoker*. Discuss the benefits/drawbacks of using the Probit model when trying to explain a binary variable.

(b) **(5 marks)** Explain briefly how the Probit estimates are obtained and discuss the properties of the parameter estimates.

Hint: You may recall that for the Probit model, we will specify

$$\Pr(\textit{smoker} = 1) = \Phi\left(\beta_0 + \beta_1 \textit{smkban} + \beta_2 \textit{female} + ... + \beta_8 E3 + \beta_9 E4\right)$$

where Φ is the standard normal CDF (cumulative distribution function).

(c) **(5 marks)** Explain how you can estimate the effect of the smoking ban on the probability of smoking for a 50-year old white, college graduated man. You are not expected to use your calculator, clarity of the computations required is enough.

(d) **(5 marks)** Discuss how you could test the joint significance of the worker's characteristics (gender, age, ethnicity and level of education) using the likelihood ratio test. Clearly indicate the test statistic, its distribution, the rejection rule and the additional information you would need to implement it.

8. An economist is interested in estimating the production function for widgets which is postulated to follow a Cobb-Douglas specification:

$$Y_i = \exp(\beta_0) L_i^{\beta_L} K_i^{\beta_K} \exp(u_i),$$

where Y_i is a measure of output for firm i, L_i is labor, K_i is capital stock and u_i is an unobserved term that captures technological or managerial efficiency and other external factors (e.g., weather). The parameters to be estimated are $(\beta_0, \beta_L, \beta_K)$. Taking logs,

$$\ln Y_i = \beta_0 + \beta_L \ln L_i + \beta_K \ln K_i + u_i.$$

(a) **(5 marks)** Provide the interpretation of the parameter β_L. What effect, if any, will changing the units of measurement of labor have on the parameter estimates for $(\beta_0, \beta_L, \beta_K)$? Explain your answer.

(b) **(5 marks)** Assume that you have a cross-section of firms and that more productive firms hire less workers (labor). Explain why OLS would not provide consistent estimates for $(\beta_0, \beta_L, \beta_K)$. Would it over- or underestimate β_L on average? Clearly explain your answer.

Instead of applying OLS, the economist decides to use the average wage paid by firm i, W_i, as an instrument for the (log) quantity of labor employed by that firm, $\ln L_i$.

(c) **(7 marks)** Describe in detail how you would estimate the parameters of the production function using Two Stage Least Squares (TSLS). What restrictions would be necessary for this researcher to successfully use this instrumental variable in the estimation of the parameters $(\beta_0, \beta_L, \beta_K)$ and what would you need to assume about capital stock?

(d) **(3 marks)** If average wages per firm do not vary much by firm (potentially because of unionization or high mobility of the labor force), how would this affect the properties of the estimation procedure suggested in (c)? Explain your answer.

9. Let us consider the expectations augmented Phillips curve (see also Mankiw, 1994):

$$\textit{infl}_t - \textit{infl}_t^e = \beta_1 (\textit{unem}_t - \mu_0) + e_t,$$

where μ_0 is the natural rate of unemployment (assumed to be constant over time) and $\textit{infl}_t^e$ is the expected rate of inflation formed in $t-1$.

This model suggests that there is a tradeoff between unanticipated inflation ($\textit{infl}_t$-$\textit{infl}_t^e$) and cyclical unemployment (difference between actual unemployment and the natural rate of unemployment). We assume that e_t (also called supply shock) is an i.i.d. random variable with zero mean.

(a) **(2 marks)** You are told that expectations are formed as follows

$$\textit{infl}_t^e - \textit{infl}_{t-1}^e = \lambda \left(\textit{infl}_{t-1} - \textit{infl}_{t-1}^e \right)$$

What name do we give such a process and how should we interpret λ?

(b) **(7 marks)** Show that you can rewrite the model as

$$\Delta \textit{infl}_t = \gamma_0 + \gamma_1 \textit{unem}_t + \gamma_2 \textit{unem}_{t-1} + v_t, \qquad (9.1)$$

where $\Delta \textit{infl}_t = \textit{infl}_t - \textit{infl}_{t-1}$. Clearly indicate the relation between $(\gamma_0, \gamma_1, \gamma_2)$ and $(\mu_0, \beta_1, \lambda)$ and show that

$$v_t = e_t - (1 - \lambda) e_{t-1}.$$

Hint: If you want you may use the following shorthand notation in your derivations: $y_t = \textit{infl}_t$, $y_t^e = \textit{infl}_t^e$ and $x_t = \textit{unem}_t$.

(c) **(3 marks)** Discuss what assumptions you would like to make about e_t (the supply shock) that will guarantee that the OLS estimator for the parameters in (9.1) is consistent. *Hint*: You may want to give the assumptions you need to make about v_t (composite error term) first.

(d) **(3 marks)** Show how you can obtain a consistent estimator for λ using your consistent estimates for $(\gamma_0, \gamma_1, \gamma_2)$? Provide a proof of its consistency. [*Note:* If you did not manage to get an explicit relation between λ and $(\gamma_0, \gamma_1, \gamma_2)$, consider $\lambda = g(\gamma_0, \gamma_1, \gamma_2)$ where $g(\cdot)$ is some continuous function].

(e) **(5 marks)** One of the assumptions provided in (c) is rather unreasonable (*Hint*: future unemployment may be related to current supply shocks). Discuss how you could use IV (TSLS) to obtain a consistent estimator for the parameters in (9.1). Discuss what conditions you instruments need to satisfy and propose a suitable instrument in this setting.

10. This question is based on "Capital Accumulation and Growth: A New Look at the Empirical Evidence", by Bond et al. (*Journal of Applied Econometrics*, 2010). In this article, the authors are interested in a regression model for the (logarithm of) output-per-capita y_t in a given country and time period t similar to:

$$y_t = \alpha + \rho y_{t-1} + \beta x_t + \gamma t + \varepsilon_t, \ \ |\rho| < 1, \tag{10.1}$$

where x_t is (the logarithm of) investment-per output. Imagine that investment rates are also affected by current output-per-capita, so that

$$x_t = \varphi_0 + \varphi_1 y_t + u_t. \tag{10.2}$$

Equations (10.1) and (10.2) then form a simultaneous equation model. Both errors ε_t and u_t have zero mean.

For (a) and (b), we start by assuming that ε_t and u_t are not serially correlated.

(a) **(5 marks)** Obtain the reduced form equations for y_t and x_t (Note: the variables t and y_{t-1} are exogenous). Are equations (10.1) and (10.2) identified? Discuss.

(b) **(5 marks)** Assume that $x_t = \varphi_0 + u_t$ (that is $\varphi_1 = 0$). Under what conditions is the OLS estimator for the parameters in the structural equation for output-per-capita (i.e., equation (10.1)) consistent? Discuss.

(c) **(5 marks)** Assume that $x_t = \varphi_0 + u_t$ (that is $\varphi_1 = 0$), u_t is not serially correlated, and $\gamma = 0$. How would you test whether ε_t is serially correlated?

(d) **(5 marks)** Assume that $x_t = \varphi_0 + u_t$ (that is $\varphi_1 = 0$), $\rho = 0$ and $\gamma = 0$. Using the Dickey-Fuller test, the authors fail to reject the hypothesis of a unit root in y_t and x_t for most of the countries in their sample at usual significance levels (5%). (Note: we are no longer assuming ε_t or u_t to not be serially correlated). Explaining your answers, what can you say about the OLS estimator for
and
applied to equation (10.1)

   i. if ε_t is non-stationary and strongly dependent?
   i. if ε_t is stationary and weakly dependent?

END OF PAPER

TABLE 4. THE NORMAL DISTRIBUTION FUNCTION

The function tabulated is $\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-\frac{1}{2}t^2}\,dt$. $\Phi(x)$ is the probability that a random variable, normally distributed with zero mean and unit variance, will be less than or equal to x. When $x < 0$ use $\Phi(x) = 1 - \Phi(-x)$, as the normal distribution with zero mean and unit variance is symmetric about zero.

	0·9994		0·9999		0·99995		1·00000

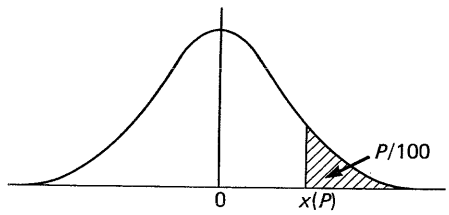
When $x > 3{\cdot}3$ the formula $1-\Phi(x) \doteqdot \dfrac{e^{-\frac{1}{2}x^2}}{x\sqrt{2\pi}}\left[1-\dfrac{1}{x^2}+\dfrac{3}{x^4}-\dfrac{15}{x^6}+\dfrac{105}{x^8}\right]$ is very accurate, with relative error less than $945/x^{10}$.

TABLE 5. PERCENTAGE POINTS OF THE NORMAL DISTRIBUTION

This table gives percentage points $x(P)$ defined by the equation

$$\frac{P}{100} = \frac{1}{\sqrt{2\pi}}\int_{x(P)}^{\infty} e^{-\frac{1}{2}t^2}\,dt.$$

If X is a variable, normally distributed with zero mean and unit variance, $P/100$ is the probability that $X \geqslant x(P)$. The lower P per cent points are given by symmetry as $-x(P)$, and the probability that $|X| \geqslant x(P)$ is $2P/100$.



P	$x(P)$	P	$x(P)$	P	$x(P)$	P	$x(P)$	P	$x(P)$	P	$x(P)$

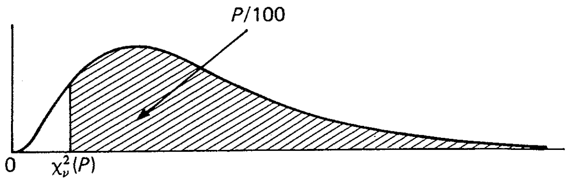
TABLE 8. PERCENTAGE POINTS OF THE χ^2-DISTRIBUTION

This table gives percentage points $\chi^2_\nu(P)$ defined by the equation

$$\frac{P}{100} = \frac{1}{2^{\nu/2}\,\Gamma(\frac{\nu}{2})} \int_{\chi^2_\nu(P)}^{\infty} x^{\frac{1}{2}\nu-1}\, e^{-\frac{1}{2}x}\, dx.$$

If X is a variable distributed as χ^2 with ν degrees of freedom, $P/100$ is the probability that $X \geqslant \chi^2_\nu(P)$.

For $\nu > 100$, $\sqrt{2X}$ is approximately normally distributed with mean $\sqrt{2\nu - 1}$ and unit variance.



(The above shape applies for $\nu \geqslant 3$ only. When $\nu < 3$ the mode is at the origin.)

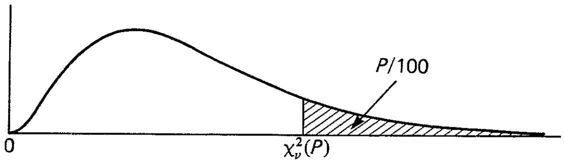
TABLE 8. PERCENTAGE POINTS OF THE χ^2-DISTRIBUTION

This table gives percentage points $\chi^2_\nu(P)$ defined by the equation

$$\frac{P}{100} = \frac{1}{2^{\nu/2}\,\Gamma(\frac{\nu}{2})} \int_{\chi^2_\nu(P)}^{\infty} x^{\frac{1}{2}\nu - 1}\, e^{-\frac{1}{2}x}\, dx.$$

If X is a variable distributed as χ^2 with ν degrees of freedom, $P/100$ is the probability that $X \geqslant \chi^2_\nu(P)$.

For $\nu > 100$, $\sqrt{2X}$ is approximately normally distributed with mean $\sqrt{2\nu - 1}$ and unit variance.



(The above shape applies for $\nu \geqslant 3$ only. When $\nu < 3$ the mode is at the origin.)

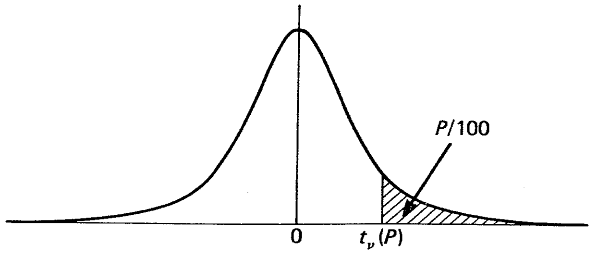
TABLE 10. PERCENTAGE POINTS OF THE t-DISTRIBUTION

This table gives percentage points $t_\nu(P)$ defined by the equation

$$\frac{P}{100} = \frac{1}{\sqrt{\nu\pi}} \frac{\Gamma(\frac{1}{2}\nu+\frac{1}{2})}{\Gamma(\frac{1}{2}\nu)} \int_{t_\nu(P)}^{\infty} \frac{dt}{(1+t^2/\nu)^{\frac{1}{2}(\nu+1)}}.$$

Let X_1 and X_2 be independent random variables having a normal distribution with zero mean and unit variance and a χ^2-distribution with ν degrees of freedom respectively; then $t = X_1/\sqrt{X_2/\nu}$ has Student's t-distribution with ν degrees of freedom, and the probability that $t \geqslant t_\nu(P)$ is $P/100$. The lower percentage points are given by symmetry as $-t_\nu(P)$, and the probability that $|t| \geqslant t_\nu(P)$ is $2P/100$.



The limiting distribution of t as ν tends to infinity is the normal distribution with zero mean and unit variance. When ν is large interpolation in ν should be harmonic.

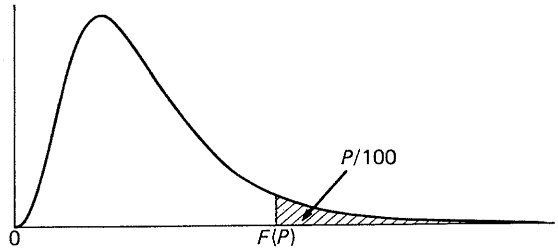
TABLE 12(*a*). 10 PER CENT POINTS OF THE *F*-DISTRIBUTION

The function tabulated is $F(P) = F(P|\nu_1, \nu_2)$ defined by the equation

$$\frac{P}{100} = \frac{\Gamma(\frac{1}{2}\nu_1 + \frac{1}{2}\nu_2)}{\Gamma(\frac{1}{2}\nu_1)\,\Gamma(\frac{1}{2}\nu_2)}\,\nu_1^{\frac{1}{2}\nu_1}\,\nu_2^{\frac{1}{2}\nu_2}\int_{F(P)}^{\infty}\frac{F^{\frac{1}{2}\nu_1 - 1}}{(\nu_2 + \nu_1 F)^{\frac{1}{2}(\nu_1+\nu_2)}}\,dF,$$

for P = 10, 5, 2·5, 1, 0·5 and 0·1. The lower percentage points, that is the values $F'(P) = F'(P|\nu_1, \nu_2)$ such that the probability that $F \leqslant F'(P)$ is equal to $P/100$, may be found by the formula

$$F'(P|\nu_1, \nu_2) = 1/F(P|\nu_2, \nu_1).$$



(This shape applies only when $\nu_1 \geqslant 3$. When $\nu_1 < 3$ the mode is at the origin.)

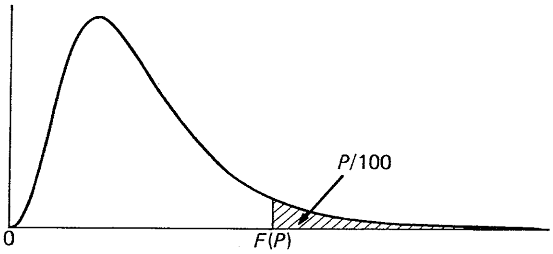
TABLE 12(*b*). 5 PER CENT POINTS OF THE *F*-DISTRIBUTION

If $F = \frac{X_1}{\nu_1} \Big/ \frac{X_2}{\nu_2}$, where X_1 and X_2 are independent random variables distributed as χ^2 with ν_1 and ν_2 degrees of freedom respectively, then the probabilities that $F \geqslant F(P)$ and that $F \leqslant F'(P)$ are both equal to $P/100$. Linear interpolation in ν_1 and ν_2 will generally be sufficiently accurate except when either $\nu_1 > 12$ or $\nu_2 > 40$, when harmonic interpolation should be used.



(This shape applies only when $\nu_1 \geqslant 3$. When $\nu_1 < 3$ the mode is at the origin.)

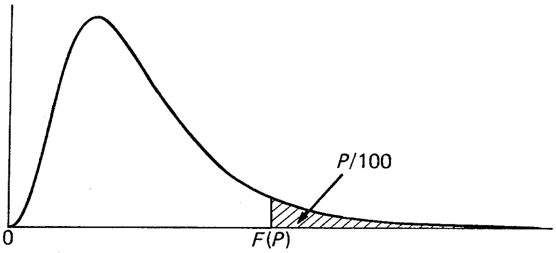
TABLE 12(*d*). 1 PER CENT POINTS OF THE *F*-DISTRIBUTION

If $F = \dfrac{X_1}{\nu_1}\Big/\dfrac{X_2}{\nu_2}$, where X_1 and X_2 are independent random variables distributed as χ^2 with ν_1 and ν_2 degrees of freedom respectively, then the probabilities that $F \geqslant F(P)$ and that $F \leqslant F'(P)$ are both equal to $P/100$. Linear interpolation in ν_1 or ν_2 will generally be sufficiently accurate except when either $\nu_1 > 12$ or $\nu_2 > 40$, when harmonic interpolation should be used.



(This shape applies only when $\nu_1 \geqslant 3$. When $\nu_1 < 3$ the mode is at the origin.)

n = number of observations

k' = number of explanatory variables

Durbin–Watson test statistic d : 5% significance points of d_L and d_U.

n	$k'=1$		$k'=2$		$k'=3$		$k'=4$		$k'=5$
